# Outline

Introduction

Heuristic Search

Greedy Search

$A^*$ -search

Admissible Heuristics

Dominance

Relaxed Problems

Summary

# Overview

**Search:** very important technique in CS and AI

Different kinds of search:

- ▶ **Deterministic search**
  - ▶ Uninformed (“blind”) search strategies ✓
  - ▶ Informed or heuristic search strategies:  
use information about problem structure
- ▶ **Local search**
- ▶ **Search in game trees** (not covered in this course)

In this lecture: **Heuristic search**

# Basic Ideas of Heuristic Search

- ▶ Use problem- or domain-specific knowledge during search
- ▶ Implemented by a **heuristic function**  $h \rightsquigarrow$  “desirability”  
(expand “most-desired” node next (= a kind of **best-first search**))
- ▶ **Evaluation function**  $f(n)$ : estimation for a function  $f^*(n)$
- ▶  $h(n)$ : estimates **minimal costs** from state  $n$  to a goal state  
( $h(n) = 0$  always holds for a goal state)
- ▶ Computation of  $h(n)$  must be easy
- ▶ Consider two algorithms:
  - ▶ **greedy search** and
  - ▶ **A\* search**

# Romania Again

Straight-line distance  
to Bucharest

<b>Arad</b>	366
<b>Bucharest</b>	0
<b>Craiova</b>	160

# Greedy Search

- ▶ Uses evaluation function  $f(n) = h(n)$
- ▶ Does **not** take already “spent” costs into account (decisions are based on **local information**)
- ▶ Example:  $h(n)$  = straight-line distance from  $n$  to Bucharest
- ▶ Greedy search expands the node with the smallest  $f$ -value (node appears to be closest to goal)

# Greedy Search for the Travel Example

Expand the only node Arad

# Greedy Search for the Travel Example

Expand the node Sibiu, because it has the smallest  $f$ -value

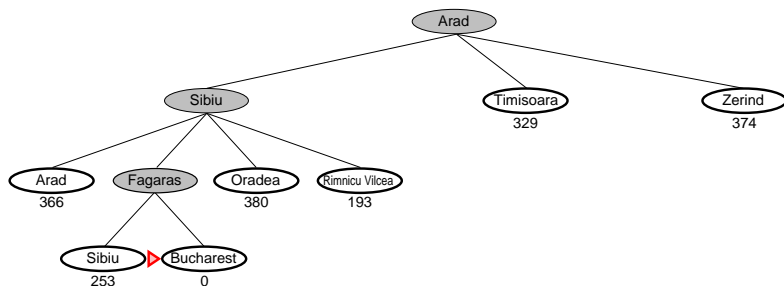

# Greedy Search for the Travel Example

Expand the node Fagaras, because it has the smallest  $f$ -value

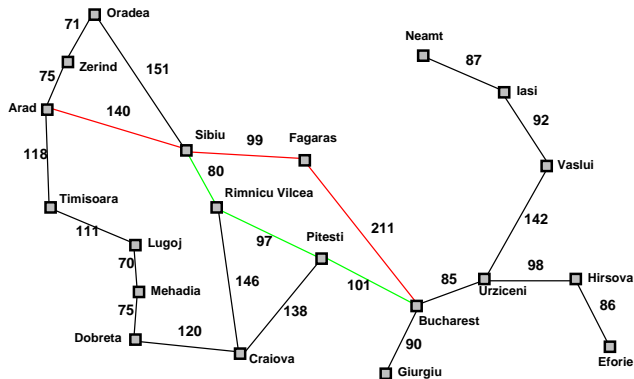

# Greedy Search for the Travel Example

**Solution found:** Arad–Sibiu–Fagaras–Bucharest (450km)

# An Alternative and Optimal Solution

Straight-line distance  
to Bucharest

<b>Arad</b>	366
<b>Bucharest</b>	0

**Non-optimal** solution: **Arad-Sibiu-Fagaras-Bucharest** (450km)  
**Arad-Sibiu-Rimnicu Vilcea-Pitesti-Bucharest** is shorter

# Properties of Greedy Search

Completeness:      No (can get stuck in loops)  
                             Yes with loop checks

Space complexity:    $O(b^m)$ , i.e., exponential in  $m$   
(keep any node)

Time complexity:     $O(b^m)$ , i.e., exponential in  $m$

Optimality:            No

# A\*-search

- ▶ Problems of greedy search: **loops** and **non-optimality** (induced by the use of **only local info**)
- ▶ **A\***: Use evaluation function  $f(n) = g(n) + h(n)$  (and avoid expanding paths that are already expensive)
  - ▶  $g(n)$ : path costs from start to  $n$ , (i.e., costs so far to reach  $n$ )
  - ▶  $h(n)$ : estimated cost to goal from  $n$  (like in greedy search)
  - ▶  $f(n)$ : estimated total cost of path through  $n$  to goal
- ▶  $h(n)$  has to be **admissible**, i.e., for all  $n$ , it holds:
  - ▶  $h(n) \leq h^*(n)$  where  $h^*(n)$  is the **true** cost from  $n$  ( $h(n)$  is “**optimistic**”)
  - ▶  $h(g) = 0$  for any goal  $g$
  - ▶  $h(n) > 0$  for any non-goal state  $n$

[http://en.wikipedia.org/wiki/A\\*\\_search\\_algorithm](http://en.wikipedia.org/wiki/A*_search_algorithm)

# A\*-search for the Travel Example

We use the **straight-line distance** to obtain an **optimistic** heuristic  
Expand the only node Arad

## A\*-search for the Travel Example

Expand the node Sibiu, because it has the smallest  $f$ -value

# A\*-search for the Travel Example

Expand the node Rimnicu Vilcea (and not Fagaras as in GS)

# A\*-search for the Travel Example

Expand the node Fagaras, because it has the smallest  $f$ -value

# A\*-search for the Travel Example

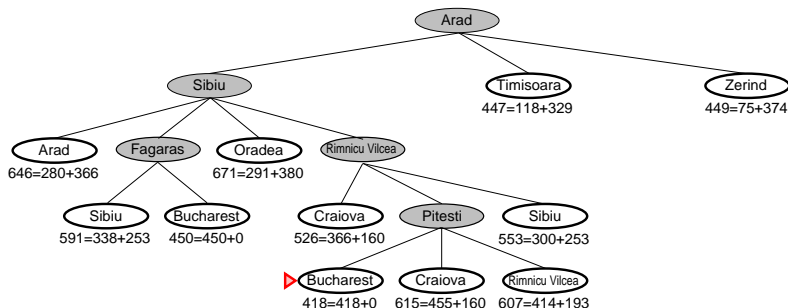

Expand the node Pitesti, because it has the smallest  $f$ -value

# A\*-search for the Travel Example

Solution: Arad–Sibiu–Rimnicu Vilcea–Pitesti–Bucharest

Since  $f$ -value of all other open nodes are bigger  $\rightsquigarrow$  terminate

# Do we Really Need Admissible Heuristics?

- ▶ S is the start state
- ▶  $h$  is **not** optimistic
- ▶ S expands immediately to G and T
- ▶  $f(G) = 5$  and  $f(T) = 7$ , so we are done
- ▶ Solution is obviously not optimal
- ▶ Hence, **heuristics must be optimistic!**

## Theorem

If  $h$  is **admissible**, then  $A^*$  using **tree search** is optimal.

## Optimality of $A^*$ : The Standard Proof

- ▶ Let  $h$  be **admissible**, goals  $G$  **optimal** and  $G_2$  **suboptimal**
- ▶ Suppose some suboptimal goal  $G_2$  has been generated
- ▶ Let  $n$  be an unexpanded node on a shortest path to  $G$

$$\begin{aligned} f(G_2) &= g(G_2) && \text{since } h(G_2) = 0 \text{ (} G_2 \text{ is a goal!)} \\ &> g(G) && \text{since } G_2 \text{ is suboptimal} \\ &\geq f(n) && \text{since } h \text{ is admissible} \end{aligned}$$

Since  $f(G_2) > f(n)$ ,  $A^*$  will **never** select  $G_2$  for expansion

# Problems with Optimality of $A^*$ Using Graph Search

- ▶  $A^*$  does **not** require for a path start– $n$  that  $g(n)$  is minimal
- ▶ No problem for tree search (there is only **one** path)
- ▶ In graph search (GS), we can reach nodes with **non-optimal** costs
- ▶ GS can discard optimal paths even if  $h$  is admissible
  - ↳ optimality is lost
- ▶ Two possibilities to fix the problem:
  - ▶ Change algorithm and add more complicated bookkeeping (But what's the effect on the run time?)
  - ▶ Impose a stronger restriction, **consistency**, on the heuristic
    - ↳ Implies that  $f$ -value is **non-decreasing** on any path

# Optimality of A\* Using Graph Search

## Definition

A heuristic is **consistent** if, for every node  $n$ , every successor  $n'$  of  $n$  and any operator  $a$ ,

$$h(n) \leq c(n, a, n') + h(n')$$

holds, where  $c(n, a, n')$  are the path costs for  $a$ .

If  $h$  is consistent, then  $f$  is non-decreasing along any path, i.e.,

$$\begin{aligned} f(n') &= g(n') + h(n') = g(n) + c(n, a, n') + h(n') \\ &\geq g(n) + h(n) = f(n) \end{aligned}$$

## Theorem

If  $h$  is **consistent**, the A\* using **graph search** is optimal

# Optimality of $A^*$

- ▶  $A^*$  expands nodes in order of increasing  $f$ -values
- ▶ The “ $f$ -contours” of nodes are added gradually (cf. BFS adds layers)
- ▶ Contour  $i$  has all nodes with  $f = f_i$ , where  $f_i < f_{i+1}$

# Properties of $A^*$

Completeness: Yes unless there are infinite many nodes with  $f \leq f(G)$

Space complexity: Exponential (Keeps all nodes in memory)

Time complexity: Exponential in  
[relative error in  $h \times$  length of solution].

Optimality: Yes

- ▶  $A^*$  expands all nodes with  $f(n) < C^*$
- ▶  $A^*$  expands some nodes with  $f(n) = C^*$
- ▶  $A^*$  expands no nodes with  $f(n) > C^*$

# Admissible Heuristics

Consider the following heuristics for the 8-puzzle:

- ▶  $h_1(n)$ : number of misplaced tiles
- ▶  $h_2(n)$ : total **Manhattan distance**  
(no. of squares ( $\leftrightarrow$  and  $\updownarrow$ ) from desired location of each tile)

7	2	4
5		6
8	3	1

Start State

1	2	3
4	5	6
7	8	

Goal State

$$h_1(\text{Start State}) = ?$$

$$h_2(\text{Start State}) = ?$$

# Admissible Heuristics

Consider the following heuristics for the 8-puzzle:

- ▶  $h_1(n)$ : number of misplaced tiles
- ▶  $h_2(n)$ : total **Manhattan distance**  
(no. of squares ( $\leftrightarrow$  and  $\updownarrow$ ) from desired location of each tile)

7	2	4
5		6
8	3	1

Start State

1	2	3
4	5	6
7	8	

Goal State

$$h_1(\text{Start State}) = 6$$

$$h_2(\text{Start State}) = 4+0+3+3+1+0+2+1 = 14$$

# Dominance

- ▶ Given two **admissible** heuristics  $h_1$  and  $h_2$
- ▶  $h_2$  **dominates**  $h_1$  (and is better for search) if  $h_2(n) \geq h_1(n)$
- ▶ Typical search costs:
  - $d = 14$  **DFIDS** requires **3,473,941** nodes
  - $A^*$  with  $h_1$  requires **539** nodes
  - $A^*$  with  $h_2$  requires **113** nodes
  - $d = 24$  **DFIDS** requires  $\approx$  **54,000,000,000** nodes
  - $A^*$  with  $h_1$  requires **39,135** nodes
  - $A^*$  with  $h_2$  requires **1,641** nodes
- ▶ Given any admissible heuristics  $h_1, h_2$ ,

$$h(n) = \max(h_1(n), h_2(n))$$

is also admissible and dominates  $h_1, h_2$

## Admissible Heuristics from Relaxed Problems

- ▶ Derive admissible heuristics from **exact** solution cost of a **relaxed** version of the problem
- ▶ If the rules of the 8-puzzle are relaxed so that a tile can move **anywhere**, then  $h_1(n)$  gives the shortest solution
- ▶ If the rules are relaxed so that a tile can move to **any adjacent square**, then  $h_2(n)$  gives the shortest solution
- ▶ **Key point:** optimal solution cost of a relaxed problem is not greater than the optimal solution cost of the real problem

## Relaxed problems cont'd

Well-known example: **traveling salesperson problem** (TSP)  
Find the shortest tour visiting all cities exactly once

**Minimum spanning tree** (MST) can be computed in  $O(n^2)$  (e.g., by the algorithms of Kruskal or Prim) and is a lower bound on the shortest (open) tour

Recall: A ST of a connected, undirected graph  $G$  is a subgraph of  $G$  which is a tree and connects all the vertices together

# Summary

- ▶ Heuristic functions estimate costs of shortest paths
- ▶ Good heuristics can dramatically reduce search cost
- ▶ Greedy best-first search expands lowest  $h$ 
  - ▶ Incomplete and not always optimal
- ▶  $A^*$  search expands lowest  $g + h$ 
  - ▶ Complete and optimal but space complexity exponential
  - ▶ Iterative-deepening  $A^*$  ( $IDA^*$ ) reduces space complexity to polynomial
- ▶ Admissible heuristics can be derived from exact solution of relaxed problems
