

Rule-based Systems

Uwe Egly

Vienna University of Technology
Institute of Information Systems
Knowledge-Based Systems Group

Overview

- ▶ Knowledge is often formulated in if-then manner
- ▶ We often have to deal with situations like
 - if Cond1 \wedge ... \wedge Condn then perform some actions**
- ▶ Such a statement is called **production rule** or simply **rule**
- ▶ Often given by domain experts during knowledge acquisition
- ▶ In this lecture, we deal with rule-based systems (RBSs)
 - ▶ Presentation of the fundamentals of RBSs
 - ▶ Examples for such systems used (not only) for KBSs
 - ▶ Brief description is based on **JBoss Drools**
- ▶ Next lecture: Example of a rule-based system in geodesy

Why Rules?

- ▶ Rules are easier to read than source code
- ▶ Non-programmers (esp. domain experts) can write rules
- ▶ Rules are better for describing complex systems (because rules are **declarative**)
- ▶ **Declarative** means to describe **what** to do, **not how** to do it
- ▶ Rules are often independent from each other
- ▶ Rules have no predefined sequence for the application (they do not describe the control)

What are Rules and Rule-based Systems?

- ▶ Rules may express different types of reasoning:

premise	→	conclusion	logical implication
antecedence	→	consequence	infer from given precondition
evidence	→	hypothesis	interpretation of facts
situation	→	action	situated behavior
IF	→	THEN	informal paraphrases
left-side	→	right-side	can mean anything

- ▶ Well-known successful system include
ILOG, [JBoss Drools](#), CLIPS, Ruby ROOLS, NOBRE
- ▶ Historically: Rules used for XPS (e.g., DEC's XCon et al.)
- ▶ Today: "Business Rules", in the Semantic Web or Games

Expert Systems @ DEC (1)

Initial situation (around 1975)

- ▶ VAX computers were sold especially tailored for each client
- ▶ Need for 1000 technical editors (TEs)
(=expert for configuring computer systems)
- ▶ No chance to hire them or to educate them
- ▶ Idea: Write a support program to boost efficiency of TEs
- ▶ The **program failed** because
 - ▶ the problem complexity was too high
 - ▶ there were nondeterministic solutions
 - ▶ the configuration data changed too quickly
- ▶ How to overcome these difficulties?

Expert Systems @ DEC (2)

The solution

- ▶ Develop an **expert system** (named R1 and later XCon)
 - ▶ Developed together with CMU
 - ▶ Rule-based (final version had approximately 5000 rules)
 - ▶ Configured VAX computers from customer orders
 - ▶ Success rate 99%
- ▶ Success of XCon yielded the development of further XPSs
- ▶ J. McDermott received AAAI Classic Paper Award 1999 for
R1: An Expert in the Computer Systems Domain

What is a Rule-based System?

- ▶ RBSs consists of the following parts
 - ▶ A collection of **facts**
(short term knowledge of the KB, often case-specific)
 - ▶ A collection of **rules** (i.e., one or more **rule bases**)
(long term knowledge of the KB, often domain-specific)
 - ▶ An **inference engine**
- ▶ Knowledge representation and reasoning are separated
- ▶ Two principle tasks:
 - ▶ Derive new facts
 - ▶ Determine whether a specific fact can be derived with the given rules and already known facts

Control Regimes for RBSs

- ▶ Two principle tasks imply two control regimes:
 - ▶ **Forward chaining** (data driven):
start with facts, determine applicable rules, and apply one
 - ▶ **Backward chaining** (goal oriented):
look for rules which decompose goal; solve smaller goals
- ▶ Is one better than the other?
No general answer possible (depends on the application)
- ▶ We focus on **forward chaining** systems here

The Working Memory

- ▶ Place where the **facts** (objects relevant for rules) are stored
- ▶ Consists of **Agenda** (= **Conflict Set**), **Truth Maintenance System** , **WM Event Support**, etc.
- ▶ Some **operations** on the WM are (there are much more):
 - ▶ **insert**: put a new fact into the WM
 - ▶ **retract**: delete a fact from the WM
 - ▶ **update**: update a fact already in the WM
 - ▶ **fireAllRules**: find applicable rules and fire one of them
- ▶ Example:

```
Cheese brie = new Cheese("brie");  
FactHandle bHandle = session.insert(brie);
```

The Rules

- ▶ Rules have the form shown on the right
- ▶ Each rule typically stored in own file
- ▶ Rules cannot be called directly
- ▶ Most important **attribute**:
 - ▶ **salience**: Rule priority as an int
- ▶ **LHS**: Can be highly complex (exa below)
- ▶ **RHS**:
 - ▶ Small code part (usually insert, retract, update WM data)
 - ▶ No complicated program structure
 - ▶ Keep RHS simple and readable

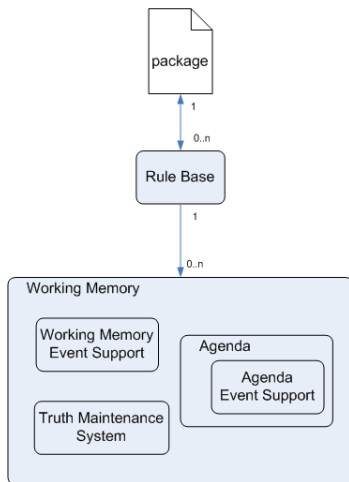

Examples for LHSs

- ▶ Cheese type is "brie" or price < 10, and age is mature
`Cheese(type=="brie" || price<10, age=="mature")`
- ▶ Check for earlier
`Cheese(bestBefore < "27-Oct-2008")`
- ▶ Return Value Restriction: `girlAge` takes age from first
`Person(girlAge : age, sex == "F")`
`Person(age == (girlAge + 2)), sex == 'M')`
- ▶ **Positive** conditions check for existence of something in WM
- ▶ **not** checks for non-existence of something in the WM
`not (Bus(color=="red") and Bus(color=="blue"))`
- ▶ With **not**, nonmonotonic behavior comes into play

Rule Bases

- ▶ Contains the rules (usually ready to run, i.e., compiled)
- ▶ Contains the WMs
- ▶ Initializes WMs (**initial facts**)
- ▶ Usually contains parts of the **inference engine**
- ▶ Usually highly configurable

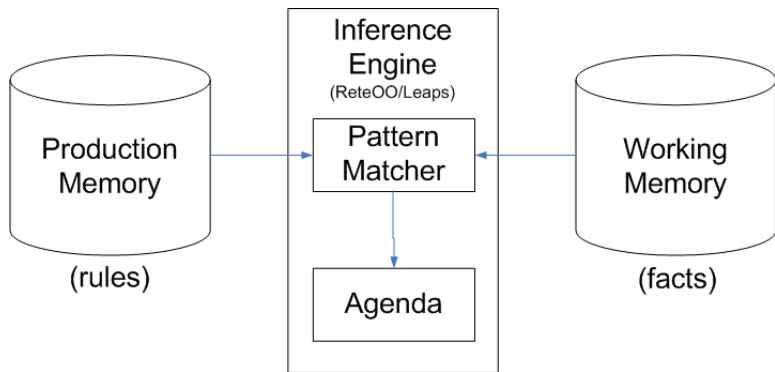

The Inference Engine

- ▶ Matches facts in the WM against rules (= productions)
- ▶ Is able to scale to a large number of rules and facts
- ▶ **Matching** determines the applicable relevant knowledge in the given situation
- ▶ **Matching** of many rules against many facts **computationally expensive** (use special algorithms like Rete, ReteOO, etc.)
- ▶ Matching often yields > 1 applicable rule (put in Agenda) (these **rule instances** are said to be in conflict)
- ▶ Use **conflict resolution** to pick one for firing
- ▶ **Firing**: executing the RHS of an applicable rule instance

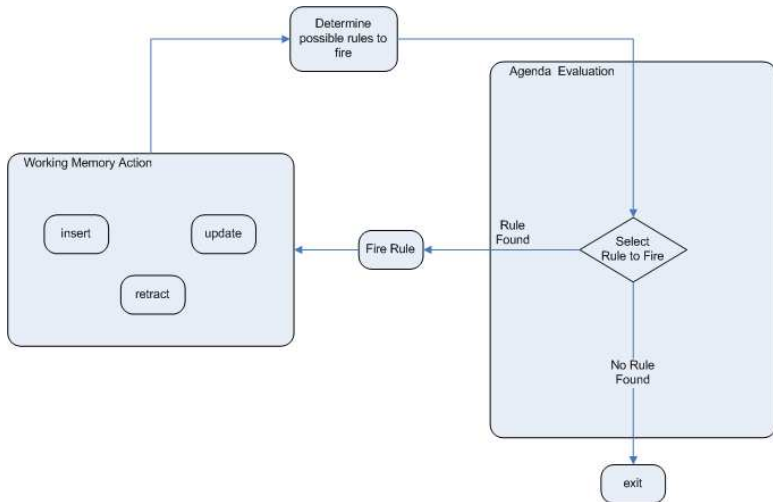

What is a Rule Instance?

- ▶ **Rule instance** consists of
 - ▶ a reference to a rule and
 - ▶ list of references to objects in WM satisfying the pos conds (positive means no not at the beginning)
- ▶ Each reference is a **witness** that corresponding cond is true (I.e., there is an object in the WM which satisfies the condition)
- ▶ Clearly, **no reference** for the **negative** conditions (why?)

An Architectural Overview of the Inference Engine

The Recognize-Act-Cycle

Conflict Resolution (CR)

- ▶ It is required if multiple rule instances are on the agenda
- ▶ Do not count on the rules firing in any particular order (In general, we represent in a **declarative** way!)
- ▶ Sometimes. **declarative** way violated for efficiency
- ▶ Standard custom conflict resolution strategies are often
 - ▶ **Salience** (=rule priority given by the knowledge engineer)
 - ▶ **LIFO**
- ▶ Custom CR strategies possible and may be based on:
 - ▶ **Specificity**:
 - Rules with more specific conditions in the LHS are preferred
 - ▶ Rule instances with **newer information** are preferred
 - ▶ Rule instances with rules recently fired are preferred
 - ▶ Or simply choose randomly

An Introductory Example

Assume that we have `Items` which are strings and `Customers` who have a `cart` (array of items)

```
Customer customer = new Customer("Fred Flinstone");
customer.addItem(new Item("brie"));
customer.addItem(new Item("cheddar"));
customer.addItem(new Item("feta"));
workingMemory.insert(customer);
```

```
rule "Msg to customers who haven't bought any brie"
when
    $c : Customer($cart : cart ->
        (!$cart.includes(new Item("brie"))))
then
    $c.sendMessage("Brie is your best friend");
end
```

A More Complicated Example: The Age Problem

An old man (O) asks a mathematician (M) to guess the ages of his three sons. Listen to their conversation:

O : The product of their ages is 36.

M : I need more information.

O : Over there you can see a building. The sum of their ages equals the number of the windows in that building.

M : I need more information.

O : The eldest son has blue eyes.

M : I got it.

What are the ages of the three sons of the old man? And how many windows does the building have? Solve the problem with a rule-based approach!

Analysis of the Age Problem

- ▶ This problem was the first one of the Drools contest (a similar one occurs in How to Solve It: Modern Heuristics by Michalewicz and Fogel)
- ▶ We discuss the solution of Elmo Nazareno (<http://ningning.org/blog2/?p=120>)
- ▶ First grasp and formalize info given by ○ (next slides)

Analysis of the Age Problem (cont'd)

- ▶ a_1 , a_2 , a_3 : the age of the youngest, middle, eldest son
- ▶ The product of their ages is 36: $a_1 \cdot a_2 \cdot a_3 = 36$
- ▶ How many such products are possible?

a_1	a_2	a_3
1	1	36
1	2	18
1	3	12
1	4	9
1	6	6
2	2	9
2	3	6
3	3	4

- ▶ We do not know the ages; can be every possibility

Analysis of the Age Problem (cont'd)

- ▶ (M) knows the number of windows, but we do not!

a_1	a_2	a_3	sum
1	1	36	38
1	2	18	21
1	3	12	16
1	4	9	14
1	6	6	13
2	2	9	13
2	3	6	11
3	3	4	10

- ▶ The solution must be one of the indicated blue lines since otherwise (M) would have the solution already
- ▶ The eldest son has blue eyes; therefore $a_1 \leq a_2 < a_3$
- ▶ How can we use this info to come up with facts and rules?

Analysis of the Age Problem (cont'd)

- ▶ (M) knows the number of windows, but we do not!

a_1	a_2	a_3	sum
1	1	36	38
1	2	18	21
1	3	12	16
1	4	9	14
1	6	6	13
2	2	9	13
2	3	6	11
3	3	4	10

- ▶ The solution must be one of the indicated blue lines since otherwise (M) would have the solution already
- ▶ The eldest son has blue eyes; therefore $a_1 \leq a_2 < a_3$
- ▶ How can we use this info to come up with facts and rules?

A Solution of the Age Problem: The Facts

- ▶ Facts are instances of objects with an attribute `age`
- ▶ Generate the facts `Son` with age i

```
for (int i = 1; i <=36; i++)  
    if ((36 % i) == 0)  
        workingMemory.insert(new Son(i));
```

A Solution of the Age Problem: The Rule (1)

Basic idea: Search for the two different ordered sequences with identical sums and choose the good sequence

- ▶ Find two different ordered sequences of three ages
- ▶ The product of each sequence must equal 36
- ▶ The sums of the two sequences must be equal
- ▶ The eldest must not have a twin

A Solution of the Age Problem: The Rule (2)

```
rule "determine ages"
when
    Son($a3: age)
    Son($a2: age < $a3)
    Son($a1: age <= $a2)

    Son($w3: age)
    Son($w2: age <= $w3)
    Son($w1: age <= $w2)

    eval($a1!=$w1 && $a2!=$w2 && $a3!=$w3)
    eval(($a1 * $a2 * $a3) == 36)
    eval(($w1 * $w2 * $w3) == 36)
    eval(($a1 + $a2 + $a3) == ($w1 + $w2 + $w3))
then
    System.out.println("eldest: " + $a3 +
        " middle: " + $a2 + " youngest: " + $a1 );
end
```

Solution of the Age Problem

- ▶ Try to figure out a solution and . . .
- ▶ answer the two questions mentioned before
- ▶ You may want to use Drools; the next slide gives a rough impression of the integration into Eclipse and some corresponding tools.
- ▶ Infos can be found using the link
`http://labs.jboss.com/drools/`
- ▶ Next lecture: a report of a KBS in geology
(to detect/classify mass movements like land slides)

Screenshot Drools in Eclipse with Rete Viewer

The screenshot displays the Eclipse IDE interface for a Drools project named "StateExampleUsingSalience.drl". The main editor shows the source code for the "StateExampleUsingSalience.drl" file, which defines a stateful rule engine with three rules: "Bootstrap", "A to B", and "B to C".

```
import org.drools.exeption.State;  
  
rule "Bootstrap"  
when  
  A : State(name == "A", state == State.NOTHING )  
then  
  System.out.println(A.getName() + " Finished");  
  A.setState( State.FINISHED );  
end  
  
rule "A to B"  
when  
  State(name == "A", state == State.FINISHED )  
  B : State(name == "B", state == State.NOTHING )  
then  
  B.setState( State.FINISHED );  
  System.out.println(B.getName() + " Finished");  
end  
  
rule "B to C"  
salience 10  
when  
  State(name == "B", state == State.FINISHED )  
  C : State(name == "C", state == State.NOTHING )  
then  
  System.out.println(C.getName() + " Finished");  
end
```

The Rete Viewer is overlaid on the code, showing a network diagram with nodes and connections. The nodes are color-coded: red for root, blue for AND nodes, green for OR nodes, and black for OR nodes. The connections represent the Rete algorithm's network structure.

The Properties window on the right shows the properties of the selected node, including "Constraint", "Evaluator", "Field Name", "Name", and "Value".

The Audit View at the bottom shows the execution history, including object assertions, activations, and state changes. The Working Memory View shows the current state of the working memory, including the state of the objects and the salience of the rules.
